were discussed and elaborated in Folding and Fracturing of Rocks in a practical way. The geometric features of folds were related to folding mechanisms and the fold related small scale structures such as cleavage, schistosity and lineation explained in terms of rock strain. Folding and Fracturing of Rocks: the background

A body of rock that is brittle—either because it is cold or because of its composition, or both— is likely to break rather than fold when subjected to stress, and the result is fracturing or faulting.

In particular, the hard igneous and metamorphic rocks that form the crystalline basement of a continent (the crust beneath layers of sediments) often behave as brittle materials, fracturing along faults during deformation, while softer sedimentary rocks that overlie them often behave as ductile materials, folding gradually.

In geology a large fracture which displays relative motion of the rockmass on either side is known as a fault. Folding is the ductile deformation (bending or squashing) of the rockmass without a...
