Abstract. In this chapter we will show you that the acceleration of an object is related to the forces acting on the object. In order to predict the motion, we need to: (i) Find what forces are acting on an object; (ii) Introduce quantitative models for the forces—we need numbers for the forces in order to have numbers for the acceleration; (iii) Determine the acceleration from the forces ...

Kinematics in One Dimension Kinematics analyzes the positions and motions of objects as a function of time, without regard to the causes of motion. It involves the relationships between the quantities displacement (d), velocity (v), acceleration (a), and time (t). The first three of these quantities are vectors.

The other two are gravity and the strong nuclear force, which is responsible for the interactions between subatomic particles and for the interactions in the nucleus. These are the three main forces in nature, and all forces are reducible to these forces. In most cases, we will study objects that consist of many atoms.

(i) Motion in one dimension Motion of an object is said to be one dimensional, if only one of the three coordinates specifying the position of the object changes with respect to time. Example : An ant moving in a straight line, running athlete, etc. Consider a particle moving on a straight line AB. For the analysis of motion we take origin.
