A considerable proportion of patients with psoriasis will develop a form of inflammatory arthritis known as psoriatic arthritis whose prevalence is poorly defined. Significant advances have been made in determining the pathophysiology of both of these diseases, with recent findings strongly implicating T cells and inflammatory cytokines such as tumor necrosis factor alpha in their pathogenesis.

Psoriatic arthritis. The pathogenesis of psoriatic arthritis (PsA) involves the following events: In joints there is a prominent lymphocytic infiltrate, limited to the dermal papillae in skin and to the underlying stroma. T lymphocytes, particularly CD4 cells, are the most common inflammatory cells in the skin and joints, with a CD4/CD8 ratio of 2:1.

Psoriatic arthritis (PsA) is a form of arthritis that occurs in patients with psoriasis. It has the hallmarks of an "inflammatory" arthritis, including joint pain, erythema, and swelling, often with prominent stiffness, not unlike the most well-characterized form of inflammatory arthritis, rheumatoid arthritis (RA).

Psoriatic Arthritis: Understanding Its Pathophysiology and ...

Psoriatic arthritis (PsA) is a chronic inflammatory arthritis of unknown etiology, and currently the cellular and molecular interactions that dictate its pathogenesis remain elusive. A role of the interleukin-23 (IL-23)/IL-23R (IL-23 receptor) interaction in the development of psoriasis and PsA is well established.

The key role of T cells in the pathogenesis of psoriatic arthritis is evidenced by a substantial increase in T-cell-derived cytokines—including interferon γ , interleukin 2, interleukin 4, TNF α , interleukin 17A, and granulocyte-macrophage colony-stimulating factor—in the synovial fluid and inflamed synovium of patients with psoriatic arthritis.

The condition may affect both peripheral joints and the axial skeleton causing pain, stiffness, swelling, and possible joint destruction. This joint pathology progresses slowly and can be more of a nuisance than disabling.

Psoriatic arthritis is a debilitating condition, which affects approximately one-quarter of psoriasis patients. Recent findings have furthered our understanding of the complex pathophysiology of PsA. There have been major advances in the identification of genes associated with joint involvement but not with cutaneous disease alone.
